Connected Stocks: Evidence from Tehran Stock Exchange

M. Heidari* S.M. Aghajanzadeh* M. Mohseni*

July, 2021

Effects

Hypothesis 1

Simple measures of institutional connnectedness statistically and economically improve forecasts of cross-sectional variation in the correlation. The effect is stronger for pairs that are in the same business groups.

	Dependent Variable: Future Monthly Correlation of 4F+Industry Residuals								
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)

Hypothesis 2

Pairs of companies belonging to the same business group have a higher correlation than pairs not in the same group. In addition, Pairs that belong to the same group and have a common ownership co-move more than pairs that don't have common ownership.

Table 1: one of these tables

Hypothesis 3

Stock returns of group affiliated firms exhibit robustly positive comovement even after controlling for both market and industry effects. Group betas $(\beta_{Businussgroup})$ are highly significant across all models.

Channels

Trading

For each firm, we calculate daily institutional imbalances, which is the net buying value of institutional investors relative to total traded value on that day (InsImb = $\frac{\text{Buy}_{\text{value}} - \text{Sell}_{\text{value}}}{\text{Buy}_{\text{value}} + \text{Sell}_{\text{value}}}$). We expect that institutional imbalances have a lower variation in groups due to the correlated tradings that the ultimate owner ordered to do. So, we calculate the monthly standard deviation of the group's imbalances and compare them to unaffiliated ones. As we expected grouped standard error is 13.1% and significantly (with t-stat of 12.57) lower than ungrouped firms.

	count	mean	std	min	median	max
Ungrouped	60	0.645	0.063	0.492	0.653	0.784
Grouped	60	0.514	0.050	0.406	0.514	0.625

According to the main hypothesis, we need to compare comovement between pairs in groups with low standard error and other pairs. For this purpose, we define **Low Imbalance std** dummy for groups whose average standard errors are lower than half of the sample. So, this dummy is equal to one if at least one pair's firms belong to the low imbalance std business group.

		Future Monthly Corr. of 4F+Ind. Residuals						
	(1)	(2)	(3)	(4)	(5)	(6)	(7)

t statistics in parentheses

Furthermore, we should show that stocks in groups have a similar daily trading behavior. Accordingly, for each firm we run time-series regressions of the firm's daily change in trading measure, $\Delta \text{Measure}_{i,t}$, on changes in market measure, $\Delta \text{Measure}_{Market,t}$, changes in the industry and business group portfolio's measure, $\Delta \text{Measure}_{Ind,t}$ and $\Delta \text{Measure}_{Group,t}$ and ,as well as control variables.

We compute the daily change of measure by this definition $\Delta \text{Measure}_{i,t} = \ln(\frac{\text{Measure}_{i,t}}{\text{Measure}_{i,t-1}})$. We estimate the following regression for each stock across trading days and cross-sectional averages of the estimated coefficients are reported, with t-statistics in parentheses:

$$\Delta \text{Measure}_{i,t} = \alpha + \beta_{Market,t} \Delta \text{Measure}_{Market,t} + \beta_{Ind,t} \Delta \text{Measure}_{Ind,t} + \beta_{Group,t} \Delta \text{Measure}_{Group,t} + \delta \text{Controls} + \varepsilon_{i,t}$$

We use the turnover and Amihud measure as a daily trading measures separately. For turnover measure, we use size of the firm as a control variable and for Amihud, we include lead, lag, and contemporaneous market returns, contemporaneous firm return squared, and lead and lag changes in the two portfolio illiquidity measures.
